

Deep bedding for swine production is a viable alternative at the small scale

Deep bedding for swine production is a viable alternative at the small scale

Performance traits of finishing pigs housed in bagasse deep bed and fed with diets based on enriched sugar cane molasses are similar compared with the pigs on concrete floor.

Summary

Deep bedding technology to the small scale for the swine production in Cuba was evaluated. Seventy two pigs YL x CC21 castrated male and female pigs (1:1) averaging 75 days of age and 21 kg live weight, were used for measuring performance traits up to slaughter weight (approximately 100 kg live weight) and also the pig carcass characteristics and animal health indexes.

The pigs were allotted according to a random blocks design with two treatments: deep bedding based on 80 % of dried sugar cane bagasse and 20 % of gramineous hay and solid concrete floor, with four repetitions per treatment. The animals of both treatments consumed NUPROVIM-75 with enriched sugar cane molasses.

There were no significant differences for the feed conversion (kg/kg), daily gain (g/day) and final weight (kg) for the pigs in deep bedding system compared with the pigs on concrete floor: 3.08, 3.06; 868, 872; 101, 101, respectively. It was saved 151 m³ of water. It was concluded that the deep bedding technology for swine production is a viable alternative at the small scale.

Key words:

Bagasse, deep bedding, enriched sugar cane molasses, performance traits
